## MANAGED GRAZING

### Manage Soil Health on Pasture and Range

It only make sense: For an industry, individual business or any human endeavor to be sustainable, it must be environmentally responsible, socially acceptable and environmentally sound. According to agronomist Steven Shafer, soil health underpins all three of these pillars of sustainability for production agriculture. To some extent, however, soil health has been taken for granted by many agricultural producers, including crop farmers and graziers. That is changing.

#### Management tips offered to stop taking soil health for granted.

"In recent years, there has been a reawakening to the importance of soil health. It's been an explosion, really, and rightly so," Shafer told cattle producers. During a Cattlemen's College educational session, Shafer, who is chief scientific officer for the Soil Health Institute, was aided by Natural Resource Conservation Service (NRCS) Grazing Lands Specialist Dennis Chessman in leading a discussion focused on management of soil health in pasture and range management systems.

"It is the soil's capacity to function as a vital, living ecosystem that sustains plants, animals and humans," said Shafer. "If we're even talking about soil 'health,' it means that soil is alive. It is very much a living system. Much of the earth's biodiversity exists in the soil."

Shafer noted how prediction models portend increasing frequency of drought in the coming decades, and the need to increase drought resistance by building

► "It is the soil's capacity to function as a vital, living ecosystem that sustains plants, animals and humans," says agronomist Steven Shafer of the Soil Health Institute.

soil health in cropping systems and grazing lands. He emphasized the value of management strategies that retain and build soil organic matter, which is composed chiefly of carbon, to increase water-holding capacity and increase retention of soil nutrients.

Specific to grazing lands, Shafer and Chessman lauded the value of management systems that foster improved plant health and enhanced growth of root biomass. Chessman emphasized that plant root exudates feed a wide variety of life forms in the soil, including bacteria, fungus, protozoa, nematodes and arthropods, and provide the "glue" that holds soils together.

► Dennis Chessman emphasized four management principles that NRCS has identified as important to promoting soil health.

Chessman emphasized four management principles that NRCS has identified as important to promoting soil health:

1. Minimize disturbance of soil surfaces, giving attention to grazing management utilizing appropriate stock density and stock movement.
2. Keep soil surfaces covered as much as

possible, by leaving sufficient residual above-ground growth.

3. Increase system diversity, moving away from monocultures to diverse plant communities.

4. Maintain and build healthy, deep plant root systems.

"We tend to focus on above-ground growth — what we can see," said Chessman. "We need to think more about what we can't see under the soil surface."

### Manage Grazing for Sustainability

What is effective grazing management? According to University of California–Davis Extension Range Management Specialist Kenneth Tate, grazing management should satisfy nutrient requirements of grazing animals. At the same time, it should satisfy the needs of forage plants for growth, reproduction and root system growth. Grazing management should also mitigate detrimental effects on soil health.

#### Stocking rate may be the most important contributor to long-term productivity of land and livestock.

Tate teamed with North Carolina grazier Johnny Rogers, who also coordinates his state's Amazing Grazing Project, to discuss sustainable grazing management concepts, during a Cattlemen's College session hosted at the 2017 Cattle Industry Convention in Nashville, Tenn.

"We must be adaptive grazing managers to be productive and care for the environment," Tate told cattle producers in attendance. "I'm not a proponent of any one strategy. All have a place," he added, emphasizing that he considers neither an intensive nor an extensive approach to be best for the sustainability of all grazing operations.

Tate said whether managers apply intensively managed rotational systems or season-long continuous grazing, stocking rate — the number of animals allocated to a pasture or paddock per unit of time — may be the most important contributor to long-term productivity of land and livestock. Tate estimates that about 75% of ranchers
